Aim
To enable women, who have had a previous caesarean section to make an informed choice for the method of birth in a subsequent pregnancy, by providing accurate information on the benefits and risks of birth after Caesarean section and repeat elective Caesarean section.
Antenatal preparation

Options

- **Elective repeat Caesarean section (ERCS)** - Planned caesarean section in a woman who has had one or more previous caesarean sections.¹

- **Planned vaginal birth after Caesarean section (VBAC)** - Planned labour with the aim of vaginal birth in a woman who has had a previous caesarean section. Also referred to as trial of labour (TOL), trial of labour after Caesarean (TOLAC), next birth after Caesarean (NBAC)¹ or labour after Caesarean (LAC).
  
  ➢ **Note:** Women with a previous classical Caesarean section, ‘inverted T’ or ‘J’ incisions, vertical lower uterine segment incision or full thickness myomectomy are excluded from this option.

Antenatal care, benefit and risk counselling recommendations¹

- Follow recommendations 1-8 (in Appendix 1: ‘RANZCOG Birth After Previous Caesarean Section’) for considerations and counselling in the antenatal period.

- In addition, KEMH specific practice requires that the final decision for mode of birth be agreed **in person** between the woman and her Obstetrician (and midwife where appropriate) before the expected/planned birthing date (ideally by 36 weeks gestation).

Success rates

- The KEMH overall vaginal birth for all women attempting VBAC is around 56% (2019)

- See pages 7-8 of RANZCOG Birth after Previous Caesarean Section college statement* for details and success rates, factors affecting success, benefits and risks of VBAC and repeat caesarean and a VBAC success prediction calculator.

Emergency Caesarean risk compared to elective Caesarean section¹

See page 11 of RANZCOG Birth after Previous Caesarean Section college statement*.

Uterine rupture counselling¹

See pages 9-10 of RANZCOG Birth after Previous Caesarean Section college statement* for uterine rupture incidence rates and perinatal complications.

* - attached as appendix
Intrapartum management

1. The senior Obstetric Registrar or Consultant and Shift Coordinator are to be notified when the woman is admitted.¹

2. Establish intravenous (IV) access¹ (leave an IV cannula in situ) and take blood for group and hold serum and/or cross matching if appropriate.

3. Attempts should be made, where possible, if not already done in the antenatal clinic, to check the operative record of the previous Caesarean section, its indication and post-operative course¹.

4. Women can have a light diet until in active labour. Once in active labour women may have sips of clear fluids¹ e.g. water, black tea or coffee, particle-free apple juice, isotonic sports drinks (NOT milk based drinks).

5. Continuous intrapartum care is required to monitor progress and to enable prompt identification and management of uterine scar rupture.¹ See FHR Monitoring guideline.

6. Vigilant assessment of progress of labour with vaginal examinations is required:
   - At least four hourly in the active phase of labour
   - Two hourly assessments from 7cm dilated
   - There needs to be evidence of progress in labour in both first and second stage. Lack of progress should trigger clinical reassessment by an experienced obstetrician.¹

7. The Cervicograph ALERT line (gradient denoting rate of 1cm / hr) becomes the ACTION line.

8. Any delay in the latent/active phase of labour, second stage or significant fetal heart rate abnormalities should be discussed immediately with the Midwifery Coordinator/ Midwifery Consultant, Obstetric Senior Registrar and/or Consultant on-call for Labour and Birth Suite. Recommendations on how to progress should be discussed with the woman and a plan for care and further assessment documented.

9. Analgesia is prescribed on request. There is no contraindication to epidural analgesia. Any concerns that epidural anaesthesia may mask symptoms of uterine rupture are not considered sufficient to contraindicate epidural use.¹

Induction and augmentation in labour¹

- See section 5.10 (pages 13-14) of RANZCOG Birth after Previous Caesarean Section college statement (appendix 1)

- If induction is required, reconsider the benefits, risks and alternatives to planned VBAC. The decision for induction should consider any other risk factors present, e.g. grand multiparity, BMI above 40 and be discussed with the Obstetric Consultant.
• Oxytocin may be used with caution in planned VBAC following discussion with the Obstetric Consultant on-call for Labour and Birth Suite with the risks and benefits discussed with the patient then documented in the clinical record.¹

• Refer also to Clinical Guideline Induction of Labour (access to WA Health employees through Healthpoint)

Electronic fetal monitoring (EFM)
See KEMH clinical guideline: Fetal Heart Rate Monitoring for monitoring options and management.

1. Women should be advised to have continuous EFM following the onset of regular uterine contractions for the duration of the planned VBAC¹ or commencement of oxytocin infusion.

2. Arrangements have been discussed prior to labour and documented in the antenatal notes using the VBAC Management Plan for Women in Labour green sticker in the Obstetric Instruction sheet (MR004) with documented Consultant involvement.

Signs and symptoms of uterine rupture
*Abnormalities in the fetal heart trace, such as variable or late decelerations, prolonged fetal bradycardia, warrant immediate review by Senior Registrar or Consultant. These abnormalities may be the first signs of scar rupture/dehiscence.

See item 5.9.9 (pages 12-13) within RANZCOG Birth after Previous Caesarean Section college statement (appendix 1) for features that raise concern of the possibility of uterine rupture.¹

Birth after previous caesarean section

This statement has been developed and reviewed by the Women’s Health Committee and approved by the RANZCOG Board and Council.

A list of Women’s Health Committee Members can be found in Appendix A.

Disclosure statements have been received from all members of this committee.

Disclaimer This information is intended to provide general advice to practitioners. This information should not be relied on as a substitute for proper assessment with respect to the particular circumstances of each case and the needs of any patient. This document reflects emerging clinical and scientific advances as of the date issued and is subject to change. The document has been prepared having regard to general circumstances.

First endorsed by RANZCOG: July 2010
Current: March 2019
Review due: March 2022

Objectives: To provide women who have previously given birth by caesarean section, their partners, doctors and midwives with information regarding the benefits and risks of their options for delivery, vaginal birth or repeat elective caesarean section.

Target audience: Health professionals providing maternity care.

Values: The evidence was reviewed by the Women’s Health Committee (RANZCOG), and applied to local factors relating to Australia and New Zealand.

Background: This statement was first developed by Women’s Health Committee in July 2010 and most recently reviewed in March 2019.

Funding: The development and review of this statement was funded by RANZCOG.

1. Terminology

- **VBAC**: Successful vaginal birth following labour in a woman who has had a prior Caesarean section delivery.

- **PLANNED VBAC**: Planned labour with a view to safe vaginal birth in a woman who has had a prior Caesarean section delivery. Also referred to by some authors as Trial of Labour (TOL) or Trial of Labour after Caesarean (TOLAC) or Next Birth after Caesarean (NBAC).

- **ERCS**: Elective repeat Caesarean section. Planned Caesarean section in a woman who has had one or more previous Caesarean sections.

- **PERINATAL MORTALITY**: The combined number of still births (antepartum and intrapartum) and neonatal deaths (death of a live infant from birth to the age of 28 days).

- **HYPOXIC ISCHAEMIC ENCEPHALOPATHY (HIE)**: Neurological changes caused by lack of sufficiently oxygenated blood perfusing brain tissue resulting in compromised neurological function manifesting during the first few days after birth. HIE may be associated with multiple organs damaged by similar perfusion injuries.

- **NEONATAL RESPIRATORY MORBIDITY**: The combined rate of transient tachypnoea of the newborn (TTN) and respiratory distress syndrome (RDS).

- **UTERINE RUPTURE**: A disruption of the uterine muscle extending to and involving the uterine serosa or disruption of the uterine muscle with extension into bladder or broad ligament.

- **UTERINE SCAR DEHISCENCE**: A disruption of the uterine muscle with intact uterine serosa.

- **PLACENTA ACCRETA**: Densely adherent placenta due to abnormally deep invasion of the placenta into the uterine muscle and sometimes growing through the full thickness of the uterine wall to the outside of the uterus.

- **LUSCS**: Lower Uterine Segment Caesarean Section.

- **RCOG**: Royal College of Obstetricians and Gynaecologists.

- **ACOG**: American Congress of Obstetricians and Gynaecologists.

- **SOGC**: Society of Obstetricians and Gynaecologists of Canada.

2. Plain language summary

Many women will need to decide on the mode of birth for subsequent pregnancies after a caesarean section. Each option – either labour with a view to safe vaginal birth, or planned Caesarean section - has both potential risks and benefits. Each individual woman's preferences and risk profiles will be different. Involvement of the woman and her family in this decision making is strongly supported. Those who provide maternity care – doctors and midwives – need to provide women and their partners with accurate and relevant information.

It can be challenging to explain and understand the risk of complications which occur rarely, but with very serious consequences when they happen. Attempting vaginal birth after a previous Caesarean section carries the additional risk for mother and baby of uterine scar rupture, an event that occurs approximately five to seven times in every 1000 attempts. If this does occur, there is approximately a one in seven chance of serious adverse outcome (death or brain injury) for the baby. When repeat elective Caesarean section is chosen there are the risks associated with major surgery, and a commitment to future Caesarean delivery is...
likely. As the number of her previous Caesarean section deliveries increases, so does the risk of rare but serious complications. The benefits and risks of each birth option and the factors affecting the chances of success for planned VBAC are discussed in this statement.

An agreed plan of management for birth should be made during a woman’s pregnancy and be documented in the medical record. Women who choose to labour with a view to the safest possible vaginal delivery should be managed in an obstetric unit with trained staff and the appropriate equipment to monitor the mother’s and fetus’ wellbeing continuously throughout the labour, and has the facility to proceed to urgent Caesarean section if required. Epidural analgesia may be used.

Some special circumstances such as women who have had more than one caesarean section, twin pregnancy and induction of labour in mid trimester are discussed.

Further information regarding birth after previous caesarean section can be found at:

https://www.ranzcoq.edu.au/Womens-Health/Patient-Information-Guides/Patient-Information-Pamphlets

3. Summary of recommendations

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Grade</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation 1</td>
<td>Consensus-based recommendation</td>
</tr>
<tr>
<td>Early in the postnatal period following a primary Caesarean delivery, women should be offered the opportunity to be debriefed and to discuss their birth experience, as well as their potential suitability for planned VBAC in future pregnancies.</td>
<td></td>
</tr>
</tbody>
</table>

| Recommendation 2 | Consensus-based recommendation |
| Women with a prior history of an uncomplicated lower segment Caesarean section, in an otherwise uncomplicated pregnancy, should be given the opportunity to discuss the birth options of planned VBAC or elective Caesarean section early in the course of their antenatal care. |

| Recommendation 3 | Consensus-based recommendation |
| The risks and benefits of the birth options, considered in conjunction with an individual woman’s chances of success for VBAC, should be discussed with the patient and documented in the medical record. The provision of a patient information leaflet or other similar resource at the consultation is recommended. |

| Recommendation 4 | Consensus-based recommendation |
| Respect should be given to the woman’s right to be involved in the decision making regarding mode of birth, considering her wishes, her perception of the risks and her plans for future pregnancies. |

| Recommendation 5 | Consensus-based recommendation |
| Attempts should be made, where possible, to check the operative record of the previous Caesarean section, its indication and post-operative course. |

| Recommendation 6 | Consensus-based recommendation |
| Women considering options for birth after a previous Caesarean section should be informed that ERCS may increase the risk of serious complications in future pregnancies. |

| Recommendation 7 | Consensus-based recommendation |
| A final decision regarding mode of birth should be agreed between the woman and her obstetrician (and midwife where appropriate) before the expected/planned delivery date (ideally by 36 weeks gestation). A plan in the event of labour starting prior to the scheduled date should be agreed and documented. |
**Recommendation 8**

Women should be advised that a planned VBAC should be conducted in a suitably staffed and equipped delivery suite, with continuous intrapartum care and monitoring and with available resources for urgent Caesarean section and neonatal resuscitation should complications such as scar rupture occur.

*Grade*

Consensus-based recommendation

**Recommendation 9**

Continuous intrapartum care is required to monitor progress and to enable prompt identification and management of uterine scar rupture.

*Grade*

Consensus-based recommendation

**Recommendation 10**

Women should be advised to have continuous electronic fetal monitoring following the onset of uterine contractions and for the duration of the planned VBAC.

*Grade*

Consensus-based recommendation

**Recommendation 11**

Epidural anaesthesia is not contraindicated in a planned VBAC.

*Grade*

Consensus-based recommendation

**Recommendation 12**

Early diagnosis of the serious complication of uterine scar rupture followed by expeditious laparotomy and resuscitation is essential to reduce the associated morbidity and mortality for mother and infant.

*Grade*

Consensus-based recommendation

**Recommendation 13**

IOL increases the risk of uterine rupture when compared to spontaneous labour or repeat CS, therefore, the risks and benefits of IOL should be considered by the clinician and discussed with the patient.

*Grade*

Consensus-based recommendation

**Recommendation 14**

Prostaglandins increase the risk of uterine rupture when compared to other methods of induction of labour, therefore, the risks and benefits of prostaglandins should be considered by the clinician and discussed with the patient.

*Grade*

Consensus-based recommendation

**Recommendation 15**

Augmentation for lack of progress in labour with oxytocin in a planned VBAC should involve discussion with an obstetrician and the risks and benefits discussed with the patient then documented in the clinical record.

*Grade*

Consensus-based recommendation

**Recommendation 16**

Mode of birth after caesarean section should be subject to multi-disciplinary clinical audit, including assessment of the number of women opting for planned VBAC versus ERCS as well as the number achieving VBAC. Quality of adherence to agreed protocols should form part of the clinical audit.

*Grade*

Consensus-based recommendation

---

4. **Introduction**

In recent decades the Caesarean section rates have continued to rise; to 33% of births in Australia in 2015 and 25.5% of births in New Zealand in 2015.\(^1\)\(^2\) As a consequence there are increasing numbers of women who need advice regarding options for birth in subsequent pregnancies. Each option, elective Caesarean section or labour with a view to vaginal birth, has its benefits and risks. Patient differences give rise to a variation of patient preference, risk spectrum and of success rates for vaginal birth. Patients and clinicians conjointly need to consider the options with a view to planning mode and place of birth for each mother who has had a previous Caesarean delivery. There are no large prospective randomised controlled trials assessing birth options.\(^3\) There are large numbers of reports which are mainly retrospective studies, predominantly originating in North America, the UK and Europe which provide some evidence of which to...
5. Discussion and recommendations

5.1 Past history and suitability for VBAC

5.1.1 That a woman should be well informed regarding mode of birth after previous Caesarean section and have the right to have her wishes respected is strongly supported by RANZCOG and other similar professional bodies.9-11

5.1.2 It is appropriate that the counselling process begins after the primary caesarean section, ideally before discharge from hospital. Ideally, it should be conducted by the doctor who performed the caesarean section and, where appropriate, the midwife who cared for the patient during her labour. The reason for the caesarean section and any unexpected issues occurring before, during or after the surgery should be discussed, particularly any that would affect the woman’s suitability for VBAC in future pregnancies. Advice which could increase the success and safety of planned VBAC, such as an inter-pregnancy (from birth to conception) interval of at least 12 months and weight reduction for overweight and obese patients should be provided.12-16 This debrief would also provide an opportunity to address any emotional needs, particularly for patients who found the experience traumatic. If a woman was not feeling ready for this discussion before discharge from hospital, a review early in the postnatal period would be worthwhile.

5.1.3 Studies of women who have faced the decision regarding mode of birth after previous caesarean delivery have reported that a significant number of women found the decision difficult—balancing their wishes against the interests of their child.17 The potential risks and benefits need to be discussed in the context of the woman’s individual circumstances, including her personal motivation and preferences to achieve vaginal birth or ERCS, her attitudes to the risk of rare but serious adverse outcomes, her plans for future pregnancies and her chances of successful VBAC.

A final decision for mode of birth should be agreed between the woman and her Obstetrician (and midwife where appropriate) before the expected/planned delivery date (ideally by 36 weeks gestation). A plan in the event of labour starting prior to the scheduled date should be agreed and documented.

Grade
Consensus-based recommendation

5.2 Success rates

5.2.1 There has been a wide range of success rates (23-85%) reported for those achieving vaginal birth following a planned VBAC.4, 6, 18, 21 Published studies of the outcomes for women attempting VBAC report a likelihood of success of between 60 and 80%.10 A study from Middlemore Hospital in New Zealand reported a 73% success rate, and one from 14 Australian hospitals reported a success rate of 43%.6, 7

5.2.2 Factors affecting success

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>More than one previous Caesarean section.</td>
</tr>
<tr>
<td></td>
<td>Risk factors associated with an increased risk of uterine scar rupture (see below).</td>
</tr>
</tbody>
</table>

5.2.3 Previous vaginal birth, especially successful VBAC, is the strongest predictor of success, with VBAC rates of 87-91% reported in that group.7, 18, 19, 23

5.2.4 Induced labour, no previous vaginal birth, a BMI greater than 30 Kg/m², and previous Caesarean section for dystocia are factors that all reduce the success rate; Landon reported if all four are present then the success rate was only 40%.18
Birth after previous Caesarean section

5.2.5 For the morbidly obese patient (BMI > 40 Kg/m²) the chances of a unsuccessful VBAC and of uterine rupture are significantly increased. Hiddard, in a prospective observational study of 14,142 patients undergoing VBAC, reported unsuccessful trial of labour in 15.2% of those of normal weight (1344 women) compared to 39.3% for those with a BMI ≥ 40 Kg/m² (1,344 women) (p<0.001), with the incidence of uterine rupture/dehiscence being 0.9% compared to 2.1% (p=0.03).

5.2.6 Other factors which have been reported to adversely affect success rates are gestational age beyond 41 weeks, fetal macrosomia, advanced maternal age, short stature, and fetal malpresentation.

Clinicians may find the online NICHD MFMU calculator for predicting successful VBAC useful. This resource can be accessed at: https://mfmunetwork.bsc.gwu.edu/PublicBSC/MFMU/VGBirthCalc/vagbirth.html

This calculator estimates likelihood of VBAC success according to variables such as maternal age, BMI, and indication for previous Caesarean section, and is based on the equation published by NICHD MFM Units Network. While other factors may influence likelihood of success, clinicians may find this calculator useful when counselling patients regarding their individualised likelihood of success.

5.3 Benefits and risks of VBAC

<table>
<thead>
<tr>
<th>BENEFITS IF SUCCESSFUL VBAC</th>
<th>RISKS</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Less maternal morbidity for index pregnancy and future pregnancies.</td>
<td>• Increased perinatal loss compared with ERCS at 39 weeks (1.8 per 1000 pregnancies)</td>
</tr>
<tr>
<td>• Avoidance of major surgery and multiple caesarean sections in future pregnancies.</td>
<td>- Stillbirth after 39 weeks gestation (due to longer gestation).</td>
</tr>
<tr>
<td>• Earlier mobilisation and discharge from hospital.</td>
<td>- Intrapartum death or neonatal death (related to scar rupture in labour).</td>
</tr>
<tr>
<td>• Patient gratification in achieving vaginal birth if this is desired.</td>
<td>• HIE risk (0.7 per 1000).</td>
</tr>
<tr>

Birth after previous caesarean section
C-Obs 38 8
5.5 Uterine rupture

5.5.1 Uterine rupture in an unscarred uterus is extremely rare, with incidence rates estimated at 0.5-2.0 per 10,000 deliveries, and occurrence mainly confined to multiparous patients in labour. The incidence of scar rupture in a patient undergoing VBAC has been reported between 22 and 74 per 10,000 births.9,33,34

5.5.2 Chauhan et al reviewed maternal and perinatal complications from 142,075 patients who attempted vaginal birth after Caesarean section delivery.35 They reported a uterine rupture rate of 6.2/1,000 trials of labour. The uterine rupture-related complication rate was 1.5 per 1,000 for pathological fetal acidosis (a cord pH < 7.00), 0.9/1000 for hysterectomy, 0.4/1,000 for perinatal death, and 0.02/1,000 for maternal death. These figures are consistent with a large Australian retrospective analysis and review of 10 international series where the likelihood of uterine rupture of attempted vaginal delivery after previous lower segment Caesarean section was estimated at 5/1,000, and the perinatal death from uterine rupture at 0.7/1,000 women attempting VBAC.4 Landon, in a prospective observational study from 19 academic centres in the United States, reported a symptomatic uterine rupture rate of 7/1,000 from a total of 17,898 women who planned VBAC, and the occurrence of HIE in seven babies related to uterine rupture (0.4/1000).33 The overall complication rates related to scar rupture per 1000 women attempting VBAC for the three series is summarised in the table below.4,33,35

**TABLE 1:** The complication rates related to scar rupture per 1000 women attempting VBAC4,33,35

</tbody>
</table>

5.5.3 A previous vaginal birth reduces the risk of uterine scar rupture.36,37

5.5.4 The risk of uterine rupture is increased with previous classical Caesarean section (20 to 90/1,000), previous ‘inverted T’ or ‘J’ incisions (19/1,000), and low vertical incision (20/1,000).9 Obtaining the record of the operative note from a previous Caesarean section to define the nature of previous scar and any significant uterine tears may be helpful in assessing the risk of future uterine rupture. A higher incidence of scar rupture has also been reported with induction of labour and augmentation of labour.5,38,41 The risk of scar rupture is further increased when prostaglandins are used to induce labour.38-40

5.5.6 A two to three-fold increase (2.3-4.8% vs 1.1-1.3%) in the incidence of scar rupture has been reported if the pregnancy interval has been less than 18 months12 or less than 24 months.12,15 There is conflicting evidence as to whether single layer compared to double layer uterine closure increases the risk of scar rupture in subsequent planned VBAC.12,42
5.5.7 Unfortunately, ultrasound measurement of myometrial thickness has not been demonstrated to be sufficiently predictive, or protective, of uterine rupture to be useful in clinical practice. Studies measuring the lower segment thickness by ultrasound in late pregnancy have reported a low incidence of subsequently detected scar defects (rupture or dehiscence) occurring with a greater frequency in patients whose ultrasound reported a very thin lower segment; however there are many other factors that can affect the incidence of uterine scar rupture.\textsuperscript{43-47}

5.6 Perinatal mortality
Women electing trial of labour have an increased risk of perinatal mortality compared to those undergoing ERCS.\textsuperscript{48} However, much of this is attributable to the often understated background rate of perinatal death after 39 weeks gestation. Where 0.4/1,000 may have a perinatal death related to uterine rupture, a further 1.4/1,000 may be expected to have an antenatal, intrapartum or neonatal death after 39 weeks gestation.\textsuperscript{35, 49} It is appropriate that this increase in perinatal mortality (1.8/1,000) be acknowledged in counselling about birth options, even though mostly not a direct consequence of uterine rupture.

5.7 Hypoxic Ischaemic Encephalopathy (HIE)
Landon reported 12 cases of HIE amongst 17,898 women undergoing planned VBAC (0.7/1,000), seven cases were related to uterine rupture and five to hypoxia in labour.\textsuperscript{33} In the same study there were no cases of HIE in 15,801 women undergoing ERCS (p < 0.001). Children with long term neurological impairment following uterine rupture have also been reported but the frequency is almost impossible to determine given the absence of long term follow-up data in these retrospective series.\textsuperscript{50, 51}

5.8 Risks associated with ERCS
While Elective Caesarean section reduces the risks of some serious adverse outcomes for the baby, the mother is exposed to surgical risks which increase with each Caesarean section that she has.

5.8.1 Neonatal perspective
Elective Caesarean section removes the risk of late perinatal loss of the baby (1.8/1000), the risk of HIE related to labour (0.7/1000) and reduces the risk of significant traumatic fetal injury. The risk of fetal injury at elective Caesarean delivery is 5/1000, with the majority (71%) being a superficial skin laceration.\textsuperscript{52} The risk of fetal intracranial injury at ERCS is very low (1:2750) when compared with assisted vaginal delivery, forceps (1:664) and vacuum (1:860), and spontaneous vaginal delivery (1:1900).\textsuperscript{53} The risk of brachial plexus injury from shoulder dystocia is significantly lower at Caesarean section.\textsuperscript{54}

When compared to vaginal birth, Caesarean section without labour has been associated with increased neonatal respiratory morbidity including transient tachypnoea of the newborn, surfactant deficiency and pulmonary hypertension. This incidence is inversely related to gestation and after 40 weeks gestation there is no difference in the incidence.\textsuperscript{55} In response to this, deferring elective caesarean delivery in uncomplicated singleton pregnancies until 39 weeks gestation or later is recommended by some international obstetric bodies.\textsuperscript{56-58}

5.8.2 Maternal perspective
Repeat elective Caesarean section exposes the mother to surgical risk in her current pregnancy, the risk increasing with each subsequent Caesarean section. In a large prospective study of 30,132 women who had caesarean delivery without labour, a total of 1202 significant complications occurred in 15,808 patients electively undergoing their second Caesarean section. As the patient’s number of caesarean deliveries increased there was statistically significant increase in the serious complications of severe haemorrhage (requiring more than four units of blood transfused).
hysterectomy, bladder and bowel injury and requirement for postoperative ventilation. Details of these findings are presented in Appendix A.

5.8.3 Subsequent pregnancies
An important issue to be considered in the decision analysis for many women is the intended future family size. Silver found that placenta accreta was present in 0.24%, 0.31%, 0.57%, 2.1% and 2.3% and 6.7% of women undergoing their first, second, third, fourth, fifth and six or more Caesarean section deliveries respectively. This is a consequence both of an increasing incidence of placenta praevia with repeated Caesarean sections and an increased likelihood of placenta accreta where the placenta is located over the uterine scar. The abnormally adherent placenta associated with placenta accreta is a potentially life threatening obstetric complication that may require interventions such as hysterectomy and high volume blood transfusion.

5.8.4 Emergency caesarean risk compared to elective caesarean section
The maternal morbidity associated with emergency Caesarean section is significantly greater than rates reported for elective Caesarean section. Severe complications were reported in 179/1355 (13.2%) emergency Caesarean sections, compared with 80/1,141 (7%) of those delivered by elective Caesarean section (p<0.001) in a prospective multicentre study from Finland. Similar results were reported in a large Canadian study of nulliparous patients comparing outcomes of 17,714 women in spontaneous labour at term with 721 women delivered by elective Caesarean section. This increased risk of associated with the emergency Caesarean delivery needs to be considered, especially for those patients with relatively low chance of successful VBAC, and particularly for those women with co-existing medical morbidities.

5.8.5 Impact on the initiation of breastfeeding
Several studies have demonstrated significantly lower rates of successful initiation of breastfeeding among women having ERCS compared to those who delivered vaginally or who have attempted vaginal birth. It is difficult to adjust for all potential confounding variables that may contribute to these results. Nevertheless, in view of these findings it is recommended that all possible steps are taken to assist women having caesarean section to initiate breastfeeding. This includes promoting skin to skin contact in theatre and supporting women to breastfeed as soon as practicable after delivery, including in recovery.

5.9 Intrapartum recommendations

<table>
<thead>
<tr>
<th>Recommendation 8</th>
<th>Grade</th>
</tr>
</thead>
<tbody>
<tr>
<td>Women should be advised that a planned VBAC should be conducted in a suitably staffed and equipped delivery suite, with continuous intrapartum care and monitoring and with available resources for urgent Caesarean section and advanced neonatal resuscitation should complications such as scar rupture occur</td>
<td>Consensus-based recommendation</td>
</tr>
</tbody>
</table>

5.9.1 All women electing to labour after previous Caesarean section should have ready access to Obstetric, Neonatal, Paediatric, Anaesthetic, operating theatre and resuscitation services (including availability of blood products) in the event that complications occur.

5.9.2 Where, by virtue of remote location, these on-site services cannot be provided, patients should be informed of limitations of services available and the implications for care should a uterine rupture occur. In most circumstances this will result in either an elective repeat Caesarean section or alternatively antenatal transfer to a centre with more comprehensive services for a trial of labour.
**Recommendation 9**

<table>
<thead>
<tr>
<th>Grade</th>
<th>Continuous intrapartum care is required to monitor progress and to enable prompt identification and management of uterine scar rupture.</th>
</tr>
</thead>
</table>

**Recommendation 10**

<table>
<thead>
<tr>
<th>Grade</th>
<th>Women should be advised to have continuous electronic fetal monitoring following the onset of uterine contractions for the duration of the planned VBAC.</th>
</tr>
</thead>
</table>

5.9.3 A woman undergoing planned VBAC should be assessed in early labour. Members of the care team should be notified in a timely manner of the admission and of the relevant clinical circumstances.

5.9.4 There should be continuous midwifery support and continuous electronic fetal monitoring.

5.9.5 Intravenous access should be established once labour is established. The conduct of labour and the possible need for blood products in an emergency situation should be considered with specific guidelines to be determined by the healthcare service.

5.9.6 Oral intake should be restricted to clear fluids because of the greater than normal probability of needing an immediate Caesarean section under general anaesthetic.

5.9.7 A trial of labour mandates vigilant assessment of progress of labour with vaginal examinations at least four hourly in the active phase of labour and more frequently as full dilatation approaches. Two hourly assessments from 7cm dilated can be helpful to detect a secondary arrest of labour. There needs to be evidence of progress in labour in both first and second stage. Lack of progress should trigger clinical reassessment by an experienced obstetrician.

**Recommendation 11**

<table>
<thead>
<tr>
<th>Grade</th>
<th>Epidural anaesthesia is not contraindicated in a planned VBAC.</th>
</tr>
</thead>
</table>

5.9.8 Any concerns that epidural anaesthesia may mask symptoms of uterine rupture are not considered sufficient to contraindicate epidural use. In the NICHD study, planned VBAC success rates were higher among women who received epidural anaesthesia compared to those who did not (73% verses 50%).

**Recommendation 12**

<table>
<thead>
<tr>
<th>Grade</th>
<th>Early diagnosis of the serious complication of uterine scar rupture followed by expeditious laparotomy and resuscitation is essential to reduce the associated morbidity and mortality for mother and infant.</th>
</tr>
</thead>
</table>

5.9.9 RCOG guidelines state, “There is no single pathognomic clinical feature that is indicative of uterine rupture but the presence of any of the following peri-partum should raise the concern of possibility of this event:

- Abnormal CTG (present in 55-87% of cases).
- Severe abdominal pain especially persisting between contractions.
- Chest pain or shoulder tip pain.
- Sudden onset of shortness of breath.
Birth after previous Caesarean section

- Acute onset of scar tenderness.
- Abnormal vaginal bleeding or haematuria.
- Cessation of previous efficient uterine activity.
- Maternal tachycardia, hypotension or shock.
- Loss of station of the presenting part. ""

5.10 Induction and augmentation in labour

</tr>
<tr>
<td>Prostaglandins increase the risk of uterine rupture when compared to other methods of induction of labour, therefore, the risks and benefits of prostaglandins should be considered by the clinician and discussed with the patient.</td>
<td>Consensus-based recommendation</td>
</tr>
<tr>
<td><strong>Recommendation 15</strong></td>
<td>Grade</td>
</tr>
<tr>
<td>Augmentation of labour with Syntocinon in planned VBAC should be performed with caution and be a consultant led discussion with the risks and benefits discussed with the patient then documented in the clinical record.</td>
<td>Consensus-based recommendation</td>
</tr>
</tbody>
</table>

5.10.1 Induction of labour for maternal or fetal indications remains an option for women undergoing planned VBAC, however induction of labour reduces the success rate of achieving VBAC and increases the rate of uterine rupture. Induced labour is less likely to result in VBAC than spontaneous labour and an unfavourable cervix at induction decreases the chances of success. 18, 40, 41, 60-63

5.10.2 In the large NICHD study of 17,898 women undergoing planned VBAC, the rates of intrapartum Caesarean section were 33%, 26% and 18% for induced, augmented and spontaneous labour groups respectively. The risk of uterine rupture per 10,000 planned VBAC’s was 102, 87, and 36 for induced, augmented and spontaneous labour groups. 18, 33

5.10.3 Several studies have reported high rates (1.4 to 2.45%) of uterine rupture when labour has been induced using prostaglandins. 33, 38, 40 Practitioners should be aware that when they prescribe prostaglandins, they will be using it against the manufacturer’s instructions and should only use it in clinical situations after obtaining and documenting informed consent from the woman.

5.10.4 Information regarding the effectiveness and safety of transcervical catheters in planned VBAC is limited due to small sample sizes in the studies and valid conclusions are not possible. 3 Two studies showed no risk of uterine rupture, whereas another reported an increased risk compared to women in spontaneous labour. 20, 40 64 It is not clear whether any increased risk may be associated with an unfavourable cervix.

5.10.5 The use of oxytocin for augmentation of contractions, separate from induction of labour during planned VBAC, has been examined in several studies. Some have found an association between oxytocin augmentation and the uterine rupture where others have not. 5,33, 62, 63 In an Australian retrospective cohort study Dekker reported a 14 fold difference in the adjusted odds ratio for uterine rupture in planned VBAC patients in spontaneous onset of labour augmented with Syntocinon (12/628, 1.9%) compared to those without augmentation with Syntocinon (16/8221, 0.19%).
5.10.6 The decision to augment labour in planned VBAC appropriately should involve a consultant Obstetrician after clinical assessment of the case and discussion with the patient. Oxytocin should be titrated in such a way that adequate uterine activity is obtained but that there be no more than four contractions in 10 minutes. Careful cervical assessments, preferably by the same person, are required to show adequate progress thereby allowing augmentation to continue. The interval for serial vaginal examinations and selected parameters of progress that would necessitate discontinuing the labour should be consultant led decisions.

5.10.7 When informing a woman about induction and/or augmentation of labour, clear information regarding potential risks and benefits should be provided. Some women who are contemplating future pregnancies may accept short term additional risks associated with induction and/or augmentation in view of the reduced risk of serious complications for future pregnancies if they achieve a successful VBAC.

Birth after previous caesarean section
C-Obs 38
14
6. Special Circumstances

6.1 Trial of labour after more than one previous caesarean section
Studies comparing outcomes of planned VBAC for patients who have had two or more Caesarean sections generally have reported significantly lower success rates for achieving VBAC, higher rates of uterine rupture or scar dehiscence, and a greater incidence of major maternal morbidity when compared to patients with only one previous Caesarean section. A meta-analysis published in 2009 reported a significantly lower success rate for VBAC (71% vs 77%, p<0.001) and higher rupture rate (1.6% vs 0.7%, p<0.001) when the outcomes of planned VBAC after two previous caesarean sections were compared to those patients with only one previous caesarean section. The meta-analysis reported a similar maternal morbidity for the patients undergoing VBAC after two previous caesarean sections compared with those undergoing a third ERCS.67 The details of some individual studies are summarised in Appendix B.

Attitudes of obstetricians and patients may vary in different regions. RCOG state that a patient with two previous uncomplicated caesarean sections in an uncomplicated pregnancy at term, “who has been fully informed by consultant Obstetrician may be considered suitable for planned VBAC”.9 However, RCOG recommends that three previous Caesarean sections is a contraindication to planned VBAC. SOGC state “available data suggests that a trial of labour with more than one previous Caesarean section is likely to be successful, but is associated with a higher risk of uterine rupture”.11

6.2 Twin Gestation
A cautious approach is advocated in twin pregnancies who are considering planned VBAC. There is some uncertainty regarding the safety and efficacy of planned VBAC in a twin pregnancy.

Success rates of vaginal birth of between 64% and 76% without an increase in scar rupture or perinatal morbidity have been reported in three small studies; Varner (n=412), Cahill (n=535) and Miller (n=210).68-70 The largest study reported a successful VBAC rate of 45% of 1850 twin pregnancies undergoing planned VBAC and a scar rupture rate of 0.9%. This study did not provide any neonatal outcome data.71

6.3 Mid-trimester delivery
Patients who have previously been delivered by Caesarean section and require delivery in the mid-trimester due to fetal abnormality or fetal demise have three options: hysterotomy; dilatation and evacuation (D&E); or, medical induction of labour. There have been no randomised trials comparing the outcomes from these options.

Misoprostol, a synthetic analogue of Prostaglandin E1, has been successful when used in the mid-trimester both for patients with an unscarred uterus and for those with a scarred uterus.72-74 Goyal, in a 2009 systematic review of 16 studies, reported an rupture rate of 1/2384 (0.04%) in patients with no uterine scar and 2/722 (0.28%) in patients with one or more prior Caesarean sections. When misoprostol was the sole agent used to induce labour (seven studies) there were no uterine ruptures in 256 patients with prior caesarean delivery. When the more recent studies of Gulec (2013) and Berghella (2009) are combined a scar rupture rate of 2/104 (1.9%) occurred in patients with one previous caesarean section and 3/79 (3.7%) in those with two or more caesarean sections. There has been a wide variation in dosage and method of administration of misoprostol in the reported series.73, 74

Due to the limitations of the studies available Dodd and Crowther in a Cochrane review 2010 entitled “Misoprostol for induction of labour to terminate pregnancy in the second or third trimester for women with a fetal abnormality or after intrauterine fetal death” stated “important information regarding maternal safety, in particular the occurrence of rare outcomes such as uterine rupture, remains limited.”75

Use of misoprostol (alone or combined with mifepristone) to induce labour in the second trimester would appear to be a reasonable option in women with prior caesarean delivery. Another option is mechanical
cervical ripening with a balloon catheter (alone or combined with mifepristone) and carefully monitored syntocinon induction of labour. The decision between these methods will be determined by gestational age, cervical favourability, number and type of caesarean section scar/s and clinician experience. These labours require close surveillance and senior clinical oversight.

7. Conclusion

Appendix D Overview of the development and review process for this statement

i. **Steps in developing and updating this statement**

This statement was originally developed in July 2010 and was most recently reviewed in March 2019. The Women’s Health Committee carried out the following steps in reviewing this statement:

- Declarations of interest were sought from all members prior to reviewing this statement.
- Structured clinical questions were developed and agreed upon.
- An updated literature search to answer the clinical questions was undertaken.
- At the February 2019 committee meeting, the existing consensus-based recommendations were reviewed and updated (where appropriate) based on the available body of evidence and clinical expertise. Recommendations were graded as set out below in Appendix B part iii)

ii. **Declaration of interest process and management**

Declaring interests is essential in order to prevent any potential conflict between the private interests of members, and their duties as part of the Women’s Health Committee.
A declaration of interest form specific to guidelines and statements was developed by RANZCOG and approved by the RANZCOG Board in September 2012. The Women’s Health Committee members were required to declare their relevant interests in writing on this form prior to participating in the review of this statement.

Members were required to update their information as soon as they become aware of any changes to their interests and there was also a standing agenda item at each meeting where declarations of interest were called for and recorded as part of the meeting minutes.

There were no significant real or perceived conflicts of interest that required management during the process of updating this statement.

iii. Grading of recommendations

Each recommendation in this College statement is given an overall grade as per the table below, based on the National Health and Medical Research Council (NHMRC) Levels of Evidence and Grades of Recommendations for Developers of Guidelines. Where no robust evidence was available but there was sufficient consensus within the Women’s Health Committee, consensus-based recommendations were developed or existing ones updated and are identifiable as such. Consensus-based recommendations were agreed to by the entire committee. Good Practice Notes are highlighted throughout and provide practical guidance to facilitate implementation. These were also developed through consensus of the entire committee.

This information has been prepared having regard to general circumstances. It is the responsibility of each practitioner to have regard to the particular circumstances of each case. Clinical management should be responsive to the needs of the individual patient and the particular circumstances of each case.

This information has been prepared having regard to the information available at the time of its preparation, and each practitioner should have regard to relevant information, research or material which may have been published or become available subsequently.

Whilst the College endeavours to ensure that information is accurate and current at the time of preparation, it takes no responsibility for matters arising from changed circumstances or information or material that may have become subsequently available.
